

Quick Facts...

The northern flicker, responsible for most woodpecker damage to Colorado homes, is identified in flight by a yellow or salmon tint under the wings and tail feathers.

Woodpeckers cause property damage by drilling holes in wood and synthetic stucco siding and eaves, and are an annoyance when hammering or “drumming” on houses.

Control damage by preventive construction, scare devices and exclusion.

WILDLIFE

Preventing Woodpecker Damage

no. 6.516

by W.F. Andelt, S.N. Hopper and M. Cerato¹

Woodpeckers are 7 to 15 inches long, have short legs, sharp-clawed toes and stiff tails. Most woodpeckers feed on wood-boring insects, insects on trees and the ground, vegetable matter, berries, or tree sap.

The northern flicker (*Colaptes auratus*), responsible for the most woodpecker damage to Colorado homes, is identified in flight by a yellow or salmon tint under the wings and tail feathers. Flickers have black spots on a tannish-white breast and belly. Males have a black or red mustache extending from the gape of the beak to below the eyes. The red-headed woodpecker (*Melanerpes erythrocephalus*), red-naped sapsucker (*Sphyrapicus nuchalis*), Williamson’s sapsucker (*Sphyrapicus thyroideus*), hairy woodpecker (*Picoides villosus*), and downy woodpecker (*Picoides pubescens*), also occasionally cause problems in Colorado.

Damage Identification

Woodpeckers cause property damage by drilling holes in wood and synthetic stucco siding and eaves, and are an annoyance when hammering or “drumming” on houses. Woodpeckers hammer to attract mates, to establish and/or defend a territory, to excavate nesting or roosting sites, and to search for insects. Wooden shingles, cedar or redwood siding, metal or plastic gutters, television antennas, chimney caps, and light posts are selected as drumming sites because these materials produce loud sounds. Drumming is most common in the spring during early morning and late afternoon and usually ends by July 1.

Control Methods

Woodpecker damage can be prevented or eliminated with several techniques including visual repellents, loud noises, exclusion, alternate construction materials, providing nesting boxes, and as a last resort, killing. Take immediate action to reduce damage because woodpeckers are not easily driven from their territories or pecking sites once they are established.

Visual Repellents

Preliminary research indicates that 7-1/2 inch diameter shaving or cosmetic mirrors that enlarge the image and hawk silhouette mobiles are successful frightening devices.

Mirrors should be placed on the side of the house where damage occurs (see Figure 1B). Attach one or two mirrors flat to the wood with the enlarging lens outward to frighten woodpeckers. Mirrors may be purchased at drug or department stores.

Hawk mobiles with a wing span of about 22 inches and a length of 11 inches, can be constructed from cardboard, 1/2 inch Styrofoam, or 1/4 inch

Since insects seldom infest well-seasoned wood in Colorado, woodpeckers hammer holes to obtain insects primarily during the first two years after house construction.

plywood (see Figure 1A). Paint black or another dark color. Hang one hawk mobile from the eave near the damaged area with monofilament line.

Black plastic strips (cut from 4 or 6 mil plastic) 1 to 1-1/2 inches wide and 2 to 3 feet long, Mylar strips, pinwheels with reflective vanes, or aluminum pie tins (preferably 12 inches in diameter), may also be placed near the damaged area to frighten woodpeckers. Allow the wind to blow the strips, pinwheels, and pie tins freely. Owl effigies generally are unsuccessful for frightening woodpeckers.

Where woodpeckers are persistent, use two or more of the above frightening devices simultaneously.

Loud Noises

Some woodpeckers are frightened away with persistent loud noises such as banging pots and pans together, firing toy cap guns, or yelling. Other woodpeckers are discouraged by deadening the sound-producing area by filling the hollow space behind the wood with expanding foam insulation. This product comes in a can and enables you to spray the foam into the hollow area. It can be purchased from hardware stores.

Other Repellents

Few chemicals that have objectionable tastes and odors are effective for repelling woodpeckers and none are currently registered for that use. Sticky bird repellents (Tanglefoot® or Roost-No-More®) applied to siding and other areas, may discourage woodpeckers because they create a tacky footing. However, some of the sticky bird repellents stain wood in hot weather, so be sure to test it on a small, out-of-sight area before applying extensively.

Exclusion

Prompt repair of large holes may encourage the woodpecker to leave or discourage other woodpeckers because these holes may serve as visual attractants. Cover the holes with aluminum flashing, tin can tops or metal sheathing, and paint them to match the siding. If damage occurs near areas that provide perch sites, eliminate these sites by covering them with metal flashing or other materials.

If a single board on the house serves as a toe hold, heavy monofilament fishing line or stainless steel wire can be tightly stretched approximately 2 inches outward across the landing site to exclude the bird.

Woodpeckers may also be excluded from damage sites under the eaves by attaching hardware cloth or plastic netting to the eaves, angling it back to the siding below the damaged area, and fastening it securely. Another method to secure netting is to fasten it under the eaves, stretch down the side of the house 3 inches from the siding, and securely attach close to the ground.

Housing Materials

Woodpeckers occasionally damage houses to obtain insects in the wood. Because insects seldom infest well-seasoned wood in Colorado, woodpeckers hammer holes to obtain insects primarily during the first two years after house construction. Insecticides or wood preservatives may deter woodpeckers by killing the insects. Woodpeckers frequently damage cedar, rough pine, redwood siding, and some synthetic stucco exterior finishing. Plywood and Masonite are less frequently damaged.

Figure 1: Hawk mobiles (A), 7-1/2-inch-diameter shaving mirrors (B), and black plastic strips (C) mounted near damage sites frighten woodpeckers. Owl effigies (D) generally are unsuccessful.

Some woodpeckers are frightened away with persistent loud noises such as banging pots and pans together, firing toy cap guns, or yelling.

Nesting woodpeckers defend their territories and keep other woodpeckers away.

Nesting Boxes

All North American woodpeckers are primarily cavity nesters that excavate their own cavities, but some species occasionally use existing cavities or nest boxes. Woodpeckers need dead or dying trees, (also known as snags), to excavate their nesting cavities. With the growth of cities, the availability of snags has decreased significantly and challenges the woodpeckers to find suitable alternatives. In the event your building is chosen, nest boxes are worth trying where other methods have

failed. Place cavity-type nest boxes on buildings in the vicinity of northern flicker damage. Nesting woodpeckers will defend their territories and keep other woodpeckers away.

For the northern flicker, construct nest boxes from wood with a 2 1/2 inch diameter entrance hole 16 to 20 inches above the floor. Inside dimensions should be about 6 x 6 inches, the total height 22 to 26 inches, and the height above ground 6 to 20 feet. A front-sloping, hinged roof will shed rain and provide easy access. Fill the box with sawdust to encourage the bird to excavate it to the desired level. Supposedly, by removing the sawdust, the bird is fooled into thinking it is constructing its own nest. Some nut meat can be added on top of the sawdust to entice the woodpecker. Place the box close to the damaged area and cover all holes drilled by woodpeckers.

If the nest box attracts European starlings, paint the interior of the box white. Starlings apparently do not like light-colored interiors. Alternatively, mount a starling-sized box near the woodpecker box and temporarily cover the woodpecker box hole to encourage the starlings to move to the smaller box.

Lethal Control

When several nonlethal control methods fail to deter nuisance woodpeckers, lethal control may be required as a last resort. Woodpeckers are classified as migratory nongame birds and are protected by the Federal Migratory Bird Treaty Act. A federal permit is required before any lethal control methods are employed. Penalties and fines are assessed to violators.

To request an application for a depredation permit, (a permit that allows you to kill a woodpecker due to property damage), call the U.S. Fish & Wildlife Service – Migratory Bird Permit Office at (303) 236-8171. The application may also be downloaded from their Web site at <http://www.fws.gov/>. Chose the “permits” section, select “migratory bird permits,” and then chose “depredation” permit application form. This form must then be submitted in writing along with the application fee.

Additionally, you must obtain Form 37 and send it with your application. Form 37 can be acquired by calling the U.S. Department of Agriculture – Wildlife Services at (303) 236-5810. You will need to explain the problem over the phone and they will then issue you a Form 37 which details the problem and includes their recommendations to the U.S. Fish & Wildlife Service.

County and city ordinances should be consulted before lethal control is employed. Pest control contractors may be helpful in catching and destroying the woodpecker if you do not want to do it yourself.
